Induction Equation: Potential Form

The induction equation is given by

$$\partial_t \mathbf{b} = \nabla \times (\mathbf{u} \times \mathbf{b}) + \eta \nabla^2 \mathbf{b}$$

Using the following identity

$$\nabla \times \nabla \times \mathbf{f} = \nabla \nabla \cdot \mathbf{f} - \nabla^2 \mathbf{f}$$

and assuming η to be constant, we use $\nabla \cdot \mathbf{b} = 0$, giving

$$\partial_t \mathbf{b} = \nabla \times (\mathbf{u} \times \mathbf{b}) - \eta \nabla \times \nabla \times \mathbf{b}.$$

Then we define a vector potential $\nabla \times \mathbf{A} \equiv \mathbf{b}$, yielding

$$\begin{aligned} \partial_t \nabla \times \mathbf{A} &= \nabla \times (\mathbf{u} \times \mathbf{b}) - \nabla \times (\eta \nabla \times \mathbf{b}) \\ \partial_t \mathbf{A} &= \mathbf{u} \times \mathbf{b} - \eta \nabla \times \mathbf{b} + \nabla \phi \end{aligned}$$

where ϕ is a scalar potential arising from “uncurling” the equation. We must then provide an additional constraint to fix ϕ : the Coulomb gauge $\nabla \cdot \mathbf{A} = 0$. Therefore

$$\begin{aligned} -\nabla \times \mathbf{b} &= -\nabla \times \nabla \times \mathbf{A} = \nabla^2 \mathbf{A}. \\ \partial_t \mathbf{A} &= \mathbf{u} \times (\nabla \times \mathbf{A}) - \eta \nabla^2 \mathbf{A} + \nabla \phi \end{aligned}$$

Next we decompose $\mathbf{u} = \mathbf{u}_0 + \mathbf{u}'$ and $\mathbf{b} = \mathbf{b}_0 + \mathbf{b}' \rightarrow \mathbf{A} = \mathbf{A}_0 + \mathbf{A}'$. We assume the mean quantities \mathbf{u}_0 and \mathbf{A}_0 are themselves solutions to the original problem. If we consider only the 0th mode of \mathbf{b} , i.e. $\mathbf{b} \cdot \hat{\mathbf{e}}_i \sim e^{i0}$ then clearly $\nabla^2 \mathbf{b} = \mathbf{0}$ and therefore

$$\partial_t \mathbf{b}' = \nabla \times (\mathbf{u}_0 \times \mathbf{b}') + \nabla \times (\mathbf{u}' \times \mathbf{b}_0) + \nabla \times (\mathbf{u}' \times \mathbf{b}').$$

Using another identity

$$\nabla \times (\mathbf{A} \times \mathbf{B}) = \mathbf{A} \nabla \cdot \mathbf{B} - \mathbf{B} \nabla \cdot \mathbf{A} + \mathbf{B} \cdot \nabla \mathbf{A} - \mathbf{A} \cdot \nabla \mathbf{B}$$

Let's check that. Using the following identity

$$\begin{aligned}
\nabla \times \nabla \times (\mathbf{u} \times \mathbf{b}) &= \nabla \times (\mathbf{u}(\nabla \cdot \mathbf{b}) - \mathbf{b}(\nabla \cdot \mathbf{u}) + (\mathbf{b} \cdot \nabla)\mathbf{u} - (\mathbf{u} \cdot \nabla)\mathbf{b}) \\
&= \nabla \times ((\mathbf{b} \cdot \nabla)\mathbf{u} - (\mathbf{u} \cdot \nabla)\mathbf{b}) \\
&= \nabla \times \left(\begin{bmatrix} \mathbf{b} \cdot \nabla u_x \\ \mathbf{b} \cdot \nabla u_y \\ \mathbf{b} \cdot \nabla u_z \end{bmatrix} - \begin{bmatrix} \mathbf{u} \cdot \nabla b_x \\ \mathbf{u} \cdot \nabla b_y \\ \mathbf{u} \cdot \nabla b_z \end{bmatrix} \right)
\end{aligned}$$

Taking the x -component gives

$$\begin{aligned}
\hat{x} \cdot \nabla \times \nabla \times (\mathbf{u} \times \mathbf{b}) &= \partial_y (\mathbf{b} \cdot \nabla u_z - \mathbf{u} \cdot \nabla b_z) - \partial_z (\mathbf{b} \cdot \nabla u_y - \mathbf{u} \cdot \nabla b_y) \\
&= \partial_y \mathbf{b} \cdot \nabla u_z + \mathbf{b} \cdot \nabla \partial_y u_z - \partial_y \mathbf{u} \cdot \nabla b_z - \mathbf{u} \cdot \nabla \partial_y b_z \\
&\quad - \partial_z \mathbf{b} \cdot \nabla u_y - \mathbf{b} \cdot \nabla \partial_z u_y + \partial_z \mathbf{u} \cdot \nabla b_y + \mathbf{u} \cdot \nabla \partial_z b_y \\
&= \mathbf{b} \cdot \nabla \omega_x - \mathbf{u} \cdot \nabla j_x \\
&\quad + \partial_y \mathbf{b} \cdot \nabla u_z - \partial_z \mathbf{b} \cdot \nabla u_y + \partial_z \mathbf{u} \cdot \nabla b_y - \partial_y \mathbf{u} \cdot \nabla b_z
\end{aligned}$$

Letting $B_0 = S = 0$, the expanded current-density equation is given by

$$\begin{aligned}
\partial_t j_x &= \eta \nabla^2 j_x \\
&\quad + \mathbf{b} \cdot \nabla \omega_x - \mathbf{u} \cdot \nabla j_x \\
&\quad + \partial_y \mathbf{b} \cdot \nabla u_z - \partial_z \mathbf{b} \cdot \nabla u_y + \partial_z \mathbf{u} \cdot \nabla b_y - \partial_y \mathbf{u} \cdot \nabla b_z \\
&= \eta \nabla^2 j_x + \hat{x} \cdot \nabla \times \nabla \times (\mathbf{u} \times \mathbf{b}).
\end{aligned}$$

by symmetry we have

$$\partial_t \mathbf{j} = \eta \nabla^2 \mathbf{j} + \nabla \times \nabla \times (\mathbf{u} \times \mathbf{b})$$

We can “uncurl” this equation, and if we assume the unknown scalar potential-gradient term $\nabla \phi = \mathbf{0}$, we have

$$\partial_t \mathbf{b} = \nabla \times (\mathbf{u} \times \mathbf{b}) + \eta \nabla^2 \mathbf{b}$$

which is the usual form of the induction equation

Navier-Stokes:

$$\partial_t \mathbf{u} + Sx\partial_y \mathbf{u} + f\hat{z} \times \mathbf{u} + [S\mathbf{u} \cdot \hat{x}]\hat{y} + \nabla p - \nu \nabla^2 \mathbf{u} - \mathbf{B} \cdot \nabla \mathbf{b} = \mathbf{b} \cdot \nabla \mathbf{b} - \mathbf{u} \cdot \nabla \mathbf{u}$$

Induction:

$$\partial_t \mathbf{A} - \nabla \phi - \eta \nabla^2 \mathbf{A} - \mathbf{u} \times \mathbf{B} - Sx\hat{y} \times \mathbf{b} = \mathbf{u} \times \mathbf{b}$$

Incompressibility and Coulomb gauge

$$\nabla \cdot \mathbf{u} = \nabla \cdot \mathbf{A} = 0$$

\mathbf{A} definition

$$\mathbf{b} = \nabla \times \mathbf{A}$$

We define the Lagrangian with multipliers $\boldsymbol{\mu}, \boldsymbol{\Lambda}, \pi, \alpha, \beta$

$$\begin{aligned} \mathcal{L} \equiv & \int_0^T \left\langle \boldsymbol{\mu} \cdot \left[\partial_t \mathbf{u} + Sx\partial_y \mathbf{u} + f\hat{z} \times \mathbf{u} + [S\mathbf{u} \cdot \hat{x}]\hat{y} + \nabla p - \nu \nabla^2 \mathbf{u} - \mathbf{B} \cdot \nabla \mathbf{b} - \mathbf{b} \cdot \nabla \mathbf{b} + \mathbf{u} \cdot \nabla \mathbf{u} \right] \right\rangle dt \\ & + \int_0^T \left\langle \boldsymbol{\Lambda} \cdot \left[\partial_t \mathbf{A} - \nabla \phi - \eta \nabla^2 \mathbf{A} - \mathbf{u} \times \mathbf{B} - Sx\hat{y} \times \mathbf{b} - \mathbf{u} \times \mathbf{b} \right] \right\rangle dt \\ & + \int_0^T \left\langle \pi \nabla \cdot \mathbf{u} \right\rangle dt + \int_0^T \left\langle \alpha \nabla \cdot \mathbf{A} \right\rangle dt + \int_0^T \left\langle \beta \cdot \left[\mathbf{b} - \nabla \times \mathbf{A} \right] \right\rangle dt \end{aligned}$$

The variation with respect to \mathbf{u}

$$\begin{aligned} \frac{\delta \mathcal{L}}{\delta \mathbf{u}} \delta \mathbf{u} = & \int_0^T \left\langle \delta \mathbf{u} \cdot \left[-\partial_t \boldsymbol{\mu} - Sx\partial_y \boldsymbol{\mu} + f\hat{z} \times \boldsymbol{\mu} + [S\boldsymbol{\mu} \cdot \hat{y}]\hat{x} + (\nabla \mathbf{u})^T \cdot \boldsymbol{\mu} - \mathbf{u} \cdot \boldsymbol{\mu} - \nu \nabla^2 \boldsymbol{\mu} - \boldsymbol{\Lambda} \times \mathbf{B} - \boldsymbol{\Lambda} \times \mathbf{b} - \nabla \pi \right] \right\rangle dt \end{aligned}$$
